23 **Introduction**

24 Improving mathematics access and outcomes in California requires that each  
25 classroom, transitional kindergarten through grade twelve (TK–12), is an equitable and  
26 engaging mathematics environment that supports all students. How a teacher creates  
27 and sustains that environment is the focus of this chapter. It expands on the five  
28 components of instructional design, introduced in chapter one, that encourage equitable  
29 outcomes and active student engagement: teaching big ideas; using open tasks;  
30 teaching toward social justice; supporting students’ questions and conjectures; and  
31 prioritizing reasoning and justification.

32 Instruction that incorporates these components can enable a diverse group of students  
33 to see themselves as mathematically capable individuals with curiosity and a love of  
34 learning that they will carry throughout their schooling.

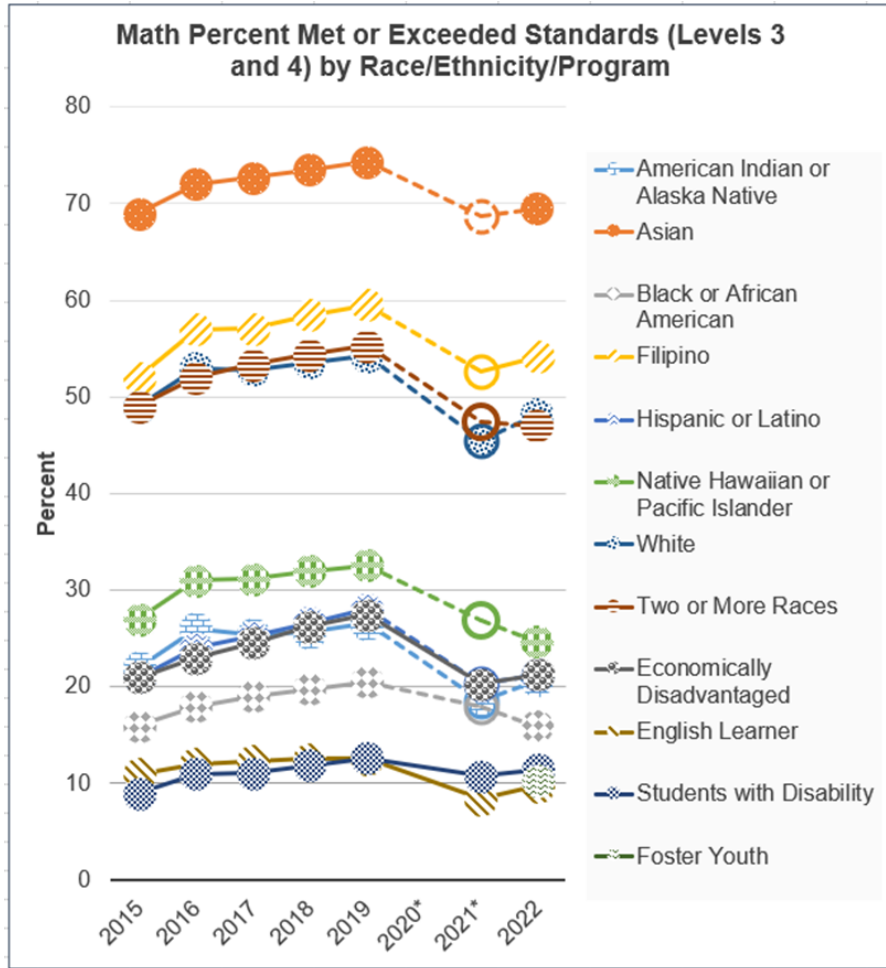

## 35 **The Need for Greater Equity and Engagement**

36 All California teachers strive to ensure that every child has an equitable opportunity to  
37 succeed. But mathematics achievement data show that, on average, this effort is not  
38 resulting in the success we want for our students. Figure 2.1 below shows data from the  
39 California Assessment of Student Performance and Progress (CAASPP) test for the  
40 2014–15 through 2021–22 school years for all students and selected sub-groups  
41 (American Indian or Alaska Native students, Asian students, Black or African American  
42 students, Filipino students, Hispanic or Latino students, Native Hawaiian or Pacific  
43 Islander students, White students, students of two or more races, economically  
44 disadvantaged students, English learners, students with disabilities, and foster youth).<sup>1</sup>  
45 Across all tested grades, about a third (33.38 percent) of all students tested in 2021–22  
46 met or exceeded the mathematics standard for their grade level—down from about 40  
47 percent of students in the 2018–19 school year, before the start of the COVID-19  
48 pandemic. The differences between White and Asian students and other student sub-  
49 groups shown in the figure are stark. Prior to the pandemic, except for White and Asian  
50 students, fewer than 30 percent of students in each sub-group met or exceeded the  
51 standard, and all groups lost ground between 2019 and 2022.

52 Figure 2.1 California Assessment of Student Performance and Progress: Percentage of  
53 Students Meeting or Exceeding Standards, Mathematics

---

<sup>1</sup> Data for the 2019–20 school year are not available because statewide assessments were suspended during the first year of the pandemic. Data for the 2020–21 school year are for the subset of students who took the CAASPP assessment in that year. See <https://www.cde.ca.gov/ta/tg/ca/documents/assessmentresultsguide21.docx> for more information.

55 Source: California Department of Education (CDE), n.d.a.

56 California high school graduation rates and the percentage of students meeting  
 57 University of California/California State University (UC/CSU) requirements also show  
 58 substantial differences among student sub-groups, as shown in figure 2.2. For example,  
 59 whereas a majority of white and Asian students met the UC/CSU requirements in 2020-  
 60 21, less than a quarter (23.98%) of graduating American Indian or Alaska Native  
 61 students and only about one third of graduating African American (30.78%) and  
 62 Hispanic or Latino (36.00%) students met the UC/CSU requirements. The data show  
 63 that although there are graduation rate disparities among student groups, the disparities  
 64 are wider with respect to UC/CSU eligibility, a finding that suggests that students'  
 65 dramatically different in-school experiences have powerful implications for their future  
 66 opportunities.

67 Figure 2.2 2021–22 Four-Year Adjusted Cohort Graduation Rate

Race/Ethnicity	Cohort Students	Cohort Graduation Rate	Percentage of Cohort Students Meeting UC/CSU Requirements
African American	26,811	78.6%	41.3%
American Indian or Alaska Native	2,580	78.8%	30.4%
Asian	47,100	95.2%	77.7%
Hispanic or Latino	273,928	84.7%	43.5%
White	111,065	90.6%	57.2%

68 Source: CDE, n.d.b.

69 At the higher education level, there are longstanding gaps among student groups in  
70 STEM enrollment and completion. While the number of female, Latino, and African  
71 American students enrolled in STEM fields in California’s public higher education  
72 system has grown over the past decade, a 2019 report found that “both nationally and in  
73 California, female and underrepresented minority (URM) students are underrepresented  
74 in STEM overall and are highly underrepresented in particular STEM fields, including  
75 engineering and computer science” (California Education Learning Lab, 2019, 2). The  
76 report found that in the UC system in 2016-17, African American students and Latino  
77 students accounted for only 1.3 percent and 15 percent, respectively, of bachelor’s  
78 degrees in STEM fields. In the CSU system, African Americans students accounted for  
79 only 2 percent and Latino students accounted for only 27 percent of bachelor’s degrees  
80 in STEM fields. (California Education Learning Lab, 2019).

81 This evidence makes clear that, on average across the state, the opportunities being  
82 provided and the approaches being employed in TK–12 classrooms, schools, and  
83 districts are not resulting in equitable student mathematics success. Across their TK–12  
84 years, students in California and across the country experience differences in  
85 opportunities to learn associated with the quality of curriculum and teaching they  
86 encounter. These differences begin early and are too often related to racial and  
87 economic inequalities in school resources (Carpenter et al., 2014; Clements and  
88 Sarama, 2014; Turner and Celedón-Pattichis, 2011). These opportunity gaps impact  
89 student outcomes differentially (Carter and Welner, 2013; Conger et al., 2009; OECD,  
90 2014; Goodman, 2019; Hanushek et al., 2019; Long et al., 2012; Reardon et al., 2018).

91 While circumstances outside of school influence equity and social mobility (Reardon,  
92 2019), the National Council of Supervisors of Mathematics (NCSM) and its affiliate  
93 organization TODOS: Mathematics for All point to data showing that school systems  
94 play a role in helping to correct the current state of math education, increase equity, and  
95 ensure the highest quality mathematics teaching and learning (NCSM and TODOS,  
96 2016). These mathematics leaders assert that equitable opportunities and outcomes for  
97 all students require systemic change. Educators at all levels need to take action to  
98 challenge deficit thinking, draw on—rather than exclude—students’ identities and

99 cultural backgrounds, and create classrooms that foster active instead of passive  
100 learning experiences.

101 To support educators in taking such action, the sections below begin by addressing  
102 three dimensions of systemic change that are particularly important for effective  
103 mathematics instruction. The bulk of the chapter then details five components of  
104 instructional design that encourage equitable outcomes and active student engagement.

## 105 **Three Dimensions of Systemic Change That Support** 106 **Mathematics Instruction**

107 Three dimensions of systemic change that are particularly important for effective  
108 mathematics instruction are: an assets-based approach to instruction; active student  
109 engagement through investigation and connection; and instruction that centers cultural  
110 and personal relevance, reflecting California’s diverse students. These practices  
111 undergird the discussion of the five components of equity and engagement that follows.

### 112 **An Assets-Based Approach to Instruction**

113 This framework asserts that California educators need opportunities to learn about,  
114 experiment with, and effectively use pedagogical approaches that recognize students’  
115 assets. Educators need to build classroom environments where all students’ ideas are  
116 valued. Resources such as the *Funds of Knowledge* framework, developed by Moll et  
117 al. (1992), support teachers in learning ways to use students’ existing skills,  
118 experiences, and (cultural) practices as a knowledge/assets base on which to attach  
119 new instructional content and experiences.

#### 120 **Building a Culture of Access and Equity**

121 “Creating, supporting, and sustaining a culture of access and equity requires being  
122 responsive to students’ backgrounds, experiences, cultural perspectives, traditions, and  
123 knowledge when designing and implementing a mathematics program and assessing its  
124 effectiveness. Acknowledging and addressing factors that contribute to differential

125 outcomes among groups of students are critical to ensuring that all students routinely  
126 have opportunities to experience high-quality mathematics instruction, learn challenging  
127 mathematics content, and receive the support necessary to be successful.

128 “Addressing equity and access includes both ensuring that all students attain  
129 mathematics proficiency and increasing the numbers of students from racial, ethnic,  
130 linguistic, gender, and socioeconomic groups who attain the highest levels of  
131 mathematics achievement.”

132 *-National Council of Teachers of Mathematics (NCTM), 2014a*

133 While more research and empirical testing of assets-based pedagogies is needed  
134 (NCTM Research Committee, 2018), existing research suggests that using students’  
135 funds of knowledge can help capture students’ imaginations and foster deeper  
136 understanding of domain knowledge (Lee, 2001; Rogoff, 2003). It can also help new  
137 learning “stick” (Hammond, 2021), increase student motivation, and perhaps support  
138 more equitable student achievement (Boykin and Noguera, 2011; NCTM Research  
139 Committee, 2018; Möller et al., 2020; Rivas-Drake et al., 2014). Given such evidence,  
140 the National Council of Teachers of Mathematics urges educators to move toward a  
141 culture of equity by enacting these pedagogies (see NCTM statement in box).

## 142 **Active Engagement Through Investigation and Connection**

143 In addition to an assets-based instructional approach, a longstanding body of research  
144 in the fields of education and psychology shows that students learn best through active  
145 engagement with mathematics and one another (Bransford et al., 2005; Freeman et al.,  
146 2014; Maaman et al., 2022; Wong et al., 2003). As discussed in chapter one, this  
147 framework highlights active engagement in classrooms by way of mathematical  
148 investigation and connection. Instructional design is guided by the why, how, and what  
149 of mathematics—for example, the three Drivers of Investigation encompass the “why” of  
150 math: to make sense of the world, predict what could happen, or impact the future. The  
151 tasks teachers design thus elicit students’ curiosity, leverage students’ knowledge, and  
152 provide motivation to engage deeply with authentic mathematics.

153 Research has produced a wealth of information showing that mathematics learning,  
154 understanding, and enjoyment comes from such active engagement with mathematical  
155 concepts—that is, when students are developing mathematical curiosity, asking their  
156 own questions, reasoning with others, and encountering mathematical ideas in  
157 multidimensional ways. This can occur through engagement with numbers but also  
158 through visuals, words, movement, and objects, and considering the connections  
159 between them (Boaler, 2019a; Cabana, Shreve, and Woodbury, 2014; Louie, 2017;  
160 Hand, 2014; Schoenfeld, 2002). The Universal Design for Learning (UDL) guidelines  
161 outline a multidimensional guide that benefits all students and can be particularly useful  
162 when applied to mathematics. (Later sections of this chapter elaborate on ways in which  
163 UDL can support equity and engagement.)

164 When students are engaged in meaningful, investigative experiences, they can come to  
165 view mathematics, and their own relationship to mathematics, far more positively. By  
166 contrast, when students sit in rows watching a teacher demonstrate methods before  
167 reproducing them in short exercise questions unconnected to real data or situations, the  
168 result can be mathematical disinterest or the perpetuation of the common perspective  
169 that mathematics is merely a sterile set of rules.

170 Students benefit from viewing mathematics as a vibrant, interconnected, beautiful,  
171 relevant, and creative set of ideas. As educators create opportunities for students to  
172 engage with and thrive in mathematics and value the different ways questions and  
173 problems can be approached and learned, many more students view themselves as  
174 belonging to the mathematics community (Boaler, 2016; Langer-Osuna, 2014; Walton et  
175 al., 2012). Such an approach prepares more students to think mathematically in their  
176 everyday lives and helps society develop many more students interested in and excited  
177 by Science, Technology, Engineering, and Mathematics (STEM) pathways.

## 178 **Cultural and Personal Relevance**

179 As noted above, California’s diverse student population brings to schools a broad range  
180 of interests, experiences, and cultural assets. Cultural and personal relevance is  
181 important for learning and also for creating mathematical communities that reflect

182 California's diversity. Educators can learn to notice, utilize, and value students'  
183 identities, assets, and cultural resources to support learning for all students.  
184 Additionally, because culture and language can be intertwined, attending to cultural  
185 relevance may also enable teachers to attend to linguistic diversity – a key feature of  
186 California and relevant to the teaching and learning of mathematics (Moschkovitch,  
187 1999, 2009, 2014).

188 This framework offers ideas for teaching in ways that create space for students with a  
189 wide range of social identities to access mathematical ideas and feel a sense of  
190 belonging to the mathematics community. A multitude of supports available to California  
191 teachers to ensure that the state's large population of language learners and  
192 multilingual students can learn and thrive include many referenced in this framework:  
193 California's English Language Development Standards (ELD Standards) (CDE, 2012),  
194 the California Department of Education's advice for integrating the ELD Standards into  
195 mathematics teaching (CDE, 2021a), the principles of UDL (CAST, 2018), and the  
196 California Department of Education's advice for asset-based pedagogies (CDE, 2021b.)  
197 Additional examples can be found in Darling's (2019) framework, including ideas about  
198 strategically grouping students for language development, making work visual, and  
199 providing opportunities for pre-learning.

## 200 **Five Components of Equitable and Engaging Teaching for All** 201 **Students**

202 California's diverse classrooms include students from a wide range of differing  
203 backgrounds whose experiences in a mathematical practice or content area also vary  
204 widely. Moreover, across backgrounds, students learn in a wide variety of ways. How  
205 does a teacher create an equitable and engaging mathematics environment that  
206 supports *all* students to reach their academic potential?

207 The following sections describe five important components of classroom instruction that  
208 can meet the needs of students who are diverse in so many ways: 1) plan teaching

209 around big ideas; 2) use open, engaging tasks; 3) teach toward social justice; 4) invite  
210 student questions and conjectures; 5) prioritize reasoning and justification.

211 Each component is based on research and supported by practice, and each is aligned  
212 with the three ideas shared above about moving toward instruction that is asset-based,  
213 supportive of students' active investigation and connection-making, and culturally and  
214 personally relevant for students. The approaches presented here are aligned with other  
215 important resources, such as the Teaching for Robust Understanding (TRU) Framework  
216 (TRU Framework, 2018), NCTM's *Catalyzing Change* series of books, as well as the  
217 *Access and Equity: Promoting High Quality Access Series* from NCTM. Relevant books  
218 include *The Impact of Identity in K–8 Mathematics* (by Julia Aguirre, Karen Mayfield and  
219 Danny B Martin), *Teaching Math to Multilingual Students* (by Kathryn Chavl and  
220 colleagues), and *Teaching Math to English Learners* (by Debra Coggins).

## 221 **Component One: Plan Teaching Around Big Ideas**

222 As discussed in chapter one, the first component of equitable, engaging teaching—  
223 planning teaching around big ideas—lays the groundwork for enacting the other four.  
224 Mathematics is a subject made up of important ideas and connections. Standards and  
225 textbooks tend to divide the subject into smaller topics, but it is important for teachers  
226 and students at each grade level to think about the big mathematical ideas and the  
227 connections between them (Nasir et al., 2014).

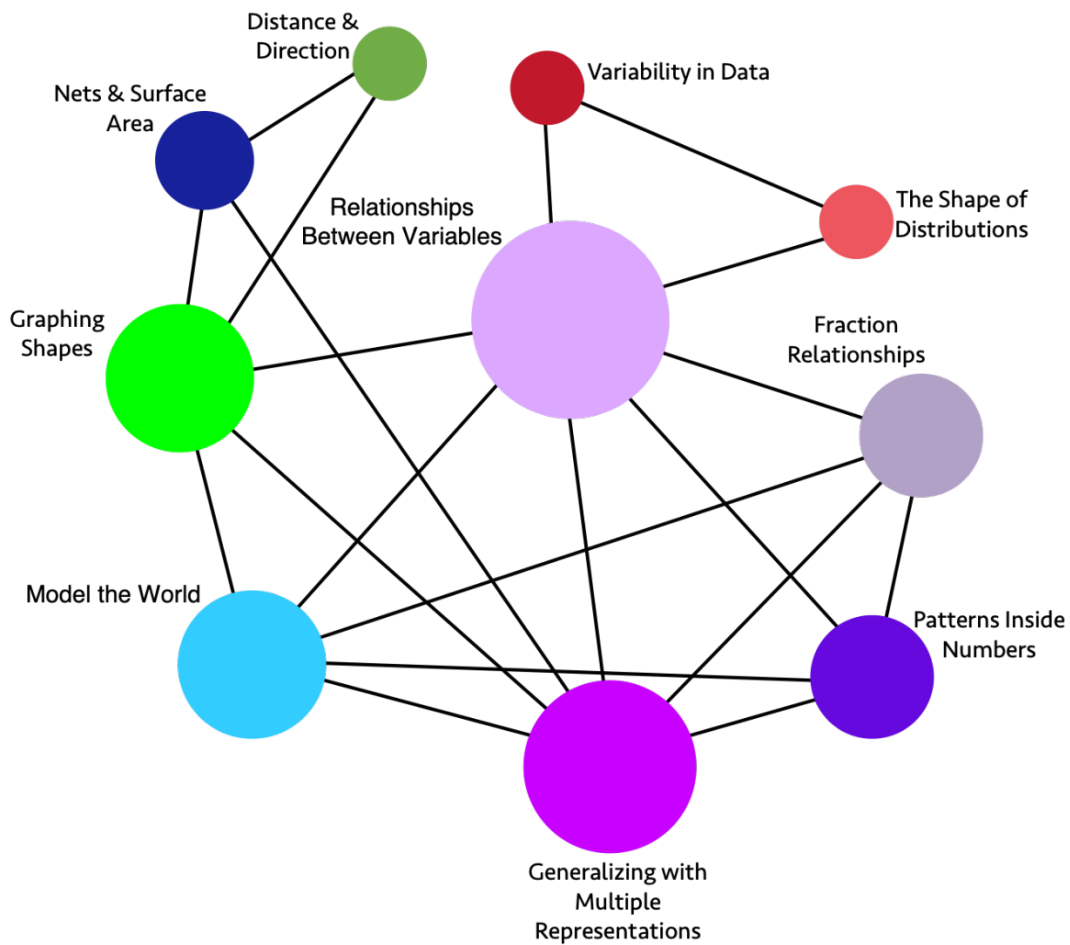

228 Planning teaching around big ideas is a way for teachers to engage students' initial  
229 understandings and draw on their diverse assets, since students may engage with and  
230 demonstrate understanding of big ideas in different ways. By planning to teach the big  
231 ideas of mathematics and designing lessons that develop important content and  
232 mathematical practices, teachers are able to build on many ideas that arise from  
233 students during instruction, draw out students' understandings, and help individuals and  
234 the class as a whole shape mathematical ideas into understandings that reflect the  
235 connected concepts and knowledge in the discipline (NASEM, 2000).

236 The big ideas approach to instruction contrasts with planning only around small,  
237 discrete, or disconnected topics in mathematics. Rather than seeking only to  
238 understand whether students can accurately demonstrate algorithmic proficiency on a  
239 single problem type, teachers hold a broader view of how students might demonstrate  
240 their mathematical knowledge and understanding. If students do not produce an  
241 expected algorithmic response, teachers look for the assets underlying their thinking, to  
242 build on what they do understand. Focusing only on small, discrete instructional topics  
243 may also limit students' ability to connect an idea with their initial understanding, and  
244 thus may interfere with their ability to grasp new concepts and information or retain  
245 conceptual understanding (NASEM, 2000).

246 Although various big ideas are present in TK–12 mathematics, and many teachers may  
247 themselves envision different major themes in the standards, this framework sets forth  
248 the notion of big idea teaching in two important ways. First, instruction is designed to  
249 connect the why, the how, and the what of mathematics, as described in chapter one.  
250 The three Drivers of Investigation (DIs) address why the math at hand is relevant. The  
251 eight Standards for Mathematical Practice (SMPs) describe how students engage with  
252 mathematics. And the four Content Connections (CCs) describe what overarching  
253 topics and connections will be learned [see below for content big ideas]).

254 Secondly, instruction is guided by a focused set of big ideas, organized by grade level  
255 and CA CCSSM content standards. Created as part of the California Digital Learning  
256 Integration and Standards Guidance initiative (CDE, 2021c), these grade level big  
257 ideas, presented in subsequent chapters, are organized by Content Connections and  
258 include multiple CA CCSSM content standards, as illustrated for grade six in figures 2.3  
259 and 2.4, below. Figure 2.3 is a network diagram of the big ideas (circular nodes) and the  
260 connections between them (line segments). Each network diagram is followed by a  
261 table such as figure 2.4 indicating the Content Connections and the relevant content  
262 standards for each big idea.

263 Figure 2.3 Grade Six Map of Big Ideas

264

265 [Long description of figure 2.3](#)

266 *Note: The sizes of the circles vary to give an indication of the relative importance of the*  
 267 *topics. The connecting lines between circles show links among topics and suggest ways*  
 268 *to design instruction so that multiple topics are addressed simultaneously.*

269 Figure 2.4 Grade Six Content Connections, Big Ideas, and Standards

Content Connection	Big Idea	Grade 6 Standards
Reasoning with Data	<b>Variability in Data</b>	<b>SP.1, SP.5, SP.4:</b> Investigate real world data sources, ask questions of data, start to understand variability - within data sets and across different forms of data, consider different types of data, and represent data with different <b>representations</b> .
Reasoning with Data	<b>The Shape of Distributions</b>	<b>SP.2, SP.3, SP.5:</b> Consider the distribution of data sets - look at their shape and consider measures of center and variability to describe the data and the situation which is being investigated.
Exploring Changing Quantities	<b>Fraction Relationships</b>	<b>NS.1, RP.1, RP.3:</b> Understand fractions divided by fractions, thinking about them in different ways (e.g., how many $\frac{1}{3}$ are inside $\frac{2}{3}$ ?), considering the relationship between the numerator and denominator, using different strategies and visuals. Relate fractions to ratios and percentages.
Exploring Changing Quantities	<b>Patterns inside Numbers</b>	<b>NS.4, RP.3:</b> Consider how numbers are made up, exploring factors and <b>multiples</b> , visually and numerically.
Exploring Changing Quantities	<b>Generalizing with Multiple Representations</b>	<b>EE.6, EE.2, EE.7, EE.3, EE.4, RP.1, RP.2, RP.3:</b> Generalize from growth or decay patterns, leading to an understanding of <b>variables</b> . Understand that a variable can represent a changing quantity or an unknown number. Analyze a mathematical situation that can be seen and solved in different ways and that leads to multiple representations and equivalent expressions. Where appropriate in solving problems, use unit rates.
Exploring Changing Quantities	<b>Relationships Between Variables</b>	<b>EE.9, EE.5, RP.1, RP.2, RP.3, NS.8, SP.1, SP.2:</b> Use independent and dependent variables to represent how a situation changes over time, recognizing unit rates when it is a <b>linear relationship</b> . Illustrate the relationship using tables, 4 quadrant graphs and equations, and understand the relationships between the different representations and what each one communicates.
Taking Wholes Apart, Putting Parts Together	<b>Model the World</b>	<b>NS.3, NS.2, NS.8, RP.1, RP.2, RP.3:</b> Solve and model real world problems. Add, subtract, multiply, and divide multi-digit numbers and decimals, in real-world and mathematical problems - with sense making and understanding, using visual models and algorithms.

Content Connection	Big Idea	Grade 6 Standards
Taking Wholes Apart, Putting Parts Together & Discovering Shape and Space	<b>Nets and Surface Area</b>	<b>EE.1, EE.2, G.4, G.1, G.2, G.3:</b> Build and decompose 3-D figures using nets to find surface area. Represent volume and area as expressions involving whole number exponents.
Discovering Shape and Space	<b>Distance and Direction</b>	<b>NS.5, NS.6, NS.7, G.1, G.2, G.3, G.4:</b> Students experience absolute value on numbers lines and relate it to distance, describing relationships, such as order between numbers using inequality statements.
Discovering Shape and Space	<b>Graphing Shapes</b>	<b>G.3, G.1, G.4, NS.8, EE.2:</b> Use coordinates to represent the vertices of polygons, graph the shapes on the coordinate plane, and determine side lengths, perimeter, and area.

270 Teachers' beliefs about mathematics influence how mathematics is taught and in turn,  
271 students' perception of the discipline. Productive beliefs enable teachers to enact  
272 effective and equitable mathematics teaching practices (NCTM, 2020). As shown in  
273 figure 2.5, it can be productive to expose students to a range of strategies and  
274 approaches for problem solving, and those are more easily elicited when teachers  
275 organize instruction around big ideas. Doing so provides students with different points of  
276 access, based on their prior knowledge. It also helps teachers move beyond the  
277 unproductive notions that mathematical ideas and understandings should be  
278 sequentially organized in the same manner for all students or that algorithms that must  
279 be memorized.

280 Figure 2.5 Beliefs About Teaching and Learning Mathematics

Unproductive beliefs	Productive beliefs
Mathematics learning should focus primarily on practicing procedures and memorizing basic number combinations.	Mathematics learning should focus on developing understanding of concepts and procedures through problem solving, reasoning, and discourse.

Unproductive beliefs	Productive beliefs
Students need only to learn and use the same standard computational algorithms and the same prescribed methods to solve algebraic problems.	All students need to have a <b>range</b> of strategies and approaches from which to choose in solving problems, including, but not limited to, general methods, <b>standard algorithms</b> , and procedures.
Students can learn to apply mathematics only after they have mastered the basic skills.	Students can learn mathematics through exploring and solving contextual and mathematical problems.

281 Source: NCTM, 2014b.

282 Rather than focusing on specific procedures and memorization, instruction is more  
 283 effective when teachers aim to develop understanding of bigger ideas and procedures.  
 284 (See also the section below on open tasks). NCTM’s *Principles to Action* (NCTM,  
 285 2014b) posits that teachers should use big mathematical ideas to establish clear goals  
 286 that guide lesson planning, instruction, and reflection. The goals help articulate the  
 287 mathematics that students are learning (in a lesson, over a series of lessons, or  
 288 throughout a unit). Teachers identify how the goals fit within a mathematics learning  
 289 progression. They help students understand instructional goals and see how the current  
 290 work contributes to their learning. Approached this way, big ideas help make learning  
 291 progressions across grade levels clearer and support coherence of the curriculum within  
 292 and across grade levels. Moreover, a focus on big ideas helps teachers identify and  
 293 utilize the assets that learners bring to the classroom and helps students see how the  
 294 range of their responses fit within a big idea.

## 295 **Component Two: Use Open, Engaging Tasks**

296 Besides linking numerous mathematics understandings into a coherent whole, the big  
 297 ideas of mathematics provide a focus for student investigations (Charles, 2005)—the  
 298 authentic activities, or projects that are the backbone of teaching the big ideas. Rather  
 299 than being focused on one way of thinking or one right answer, student investigations  
 300 rely on open tasks—that is, tasks that engage students in multidimensional exploration  
 301 and investigation, drawing from their own knowledge and interests. Open tasks enable

302 students to learn mathematics by meaningfully engaging in mathematical experiences  
303 that are visual, physical, and numerical and employ multiple representations and forms  
304 of expression (Foote and Lambert, 2011; Lambert and Sugita, 2016; Moschkovich,  
305 1999; Boaler and LaMar, 2019). For example, students can be asked to design  
306 wheelchair ramps, plan a new school garden, or survey peers to find out how they have  
307 been impacted by distance learning.

308 Open tasks allow all students to work at levels that are appropriately challenging for  
309 them, within the content of their grade. By contrast, tasks that are closed ask narrow,  
310 focused questions that include only some students in the appropriate cognitive  
311 challenges. Teachers should aim to provide tasks that have a “low floor and a high  
312 ceiling,” meaning that any student can access the task but the task allows student to  
313 extend their thinking into a range of mathematical ideas (Boaler, 2016; Krainer, 1993).

314 The math task analysis framework from Stein and colleagues (2000) shown in figure 2.6  
315 offers helpful descriptions of two types of narrow, low cognitive demand tasks—those  
316 that require only memorization or procedures without connections—and two types of  
317 open, high cognitive demand tasks—those in which students employ mathematical  
318 procedures with connections or do mathematics tasks. Too many students in California  
319 are not provided ample opportunities to consistently engage with open tasks that have  
320 high cognitive demand (The Education Trust, 2018). Yet closed tasks can still be useful  
321 to provide practice opportunities for students. Teachers should thus consider the  
322 frequency and manner in which they use closed tasks. And all tasks, regardless of their  
323 cognitive demand, should be offered based on the instructional goals.

326 The following open task example, “Four 4s,” illustrates how an open task can support  
 327 the development of big ideas, positive mathematical classroom norms, content  
 328 standards, mathematical practices, and English language development. This task may

329 be most useful for third and fourth graders, but it may also be meaningful for younger  
 330 and older students.

331 **An Open Task Example: Four 4s**

332 **Task Prompt:** How many numbers can you create that have values between 1 and 20  
 333 using exactly four 4s and any operation?

Opportunities	Supported Standards
Opportunities for Mathematics Content Learning	<p>Grade levels at which the task might be used, with (selected) <b>mathematical big ideas and associated content standards:</b></p> <ul style="list-style-type: none"> <li>• K – Being flexible within 10 (OA.1, OA.3)</li> <li>• 1 – Equal Expressions (OA.1, OA.3), Tens and Ones (NBT.3)</li> <li>• 2 – Skip Counting to 100 (NBT.3), Number Strategies (OA.1)</li> <li>• 3 – Number Flexibility to 100 (OA.1, OA.3, NBT.3), Fractions as Relationships (NF.3)</li> <li>• 4 – Fraction Flexibility (NF.3, NF.4, NF.5, OA.1), Multi-Digit Numbers (NBT 3)</li> <li>• 5 – Fraction connections (NF.3, NF.4, NF.5, NBT.3)</li> <li>• 6 – Generalizing with Multiple Representations (EE.6)</li> </ul>

Opportunities	Supported Standards
Opportunities for Language Development and Teacher Actions	<p><b>ELD Standard Part 1 – Interacting in meaningful ways</b></p> <p><b>A. Collaborative (engagement in dialogue with others)</b></p> <p>Teacher actions might include: allow time for struggle; ask:</p> <ul style="list-style-type: none"> <li>• How could you get started on this problem?</li> <li>• What does it mean that “any operation” is allowed?</li> <li>• What does this symbol (parentheses, equal sign, fraction bar) mean to you?</li> </ul>

334 Source: Youcubed, n.d.

335 Another popular example of how teachers can use open tasks is number talks. In a  
336 number talk, a teacher might ask the class of students to work out the answer to  $18 \times 5$   
337 mentally, then solicit the different answers that students may have found and write them  
338 on the board. After the different answers are collected teachers can ask if anyone would  
339 like to explain their thinking. Ideally, different students will share different ways of  
340 thinking about the problem, with visual, as well as numerical solutions. Chapter three  
341 provides further discussion of and resources for number talks. (For further guidance on  
342 implementing open tasks and on the teacher and student actions that might be  
343 demonstrated see NCTM’s *Principles to Actions* [2014]).

344 Open tasks support student engagement in mathematics in multiple ways, notably  
345 including the following three:

346 **Open tasks can support access and flexible mathematical thinking.** Open tasks  
347 have the potential to broaden access to mathematics because they are grounded in  
348 authentic and meaningful contexts—real life issues students actually wonder about—  
349 and thus provide multiple ways for students to begin thinking about the mathematics of  
350 the task. Students can engage with the mathematics through many different pathways  
351 and tools. Moreover, classroom discussions are enhanced by the range of strategies  
352 and perspectives that students offer. For example, when students discuss connections

353 between direct modeling and more abstract reasoning strategies, students who may  
354 previously have relied on one strategy benefit. Those using direct modeling approaches  
355 might start to notice connections to more abstract ideas, helping them to think more  
356 flexibly and build understanding. Similarly, students utilizing more abstract strategies  
357 benefit from conceptually connecting those ideas to more concrete representations,  
358 drawings, or even other abstract approaches. With open tasks, teachers can take an  
359 assets-based approach to understand the mathematics that students bring to a task.  
360 The diversity of mathematical thinking that then arises in the classroom can support  
361 students' conceptual understanding and strategic reasoning (National Research  
362 Council, 2001; Stein and Smith, 2018).

363 ***Open tasks can support teachers' formative assessment.*** Open tasks provide  
364 teachers with opportunities to listen carefully, make sense of student thinking, and  
365 assess formatively as the lesson progresses. Teachers can thus make in-the-moment  
366 adjustments to support student learning and differentiate instruction. Such formative  
367 assessment begins with teachers selecting a rich task and anticipating how their  
368 individual students, with diverse mathematical strengths, might access and approach  
369 the task and how they might plan their instruction accordingly (Smith and Stein, 2018).  
370 (NCTM's 2014 *Principles to Actions* offers guidance on how to select tasks and support  
371 student discussions around rich tasks.)

372 During the lesson, teachers can use classroom discourse to listen closely to students'  
373 thinking (Cirillo and Langer-Osuna, 2018). They make use of the questions they have  
374 prepared in advance to support all students to learn the content. As surprises occur,  
375 teachers can also improvise additional questions and prompts that might support  
376 emerging understanding and enable students to communicate the mathematics more  
377 coherently. In short, teachers can be responsive to each students' thinking, rather than  
378 evaluating students' thinking along narrow dimensions of success. This creates  
379 opportunities to meet students where they are in their learning, the in-the-moment work  
380 of teaching (Munson, 2018).

381 (Chapter eleven provides further discussion of how the use of open tasks enables  
382 teachers to gather important information about students' learning. Chapter twelve  
383 discusses California's evolving comprehensive assessment system that support this  
384 framework's vision of mathematics teaching and learning.)

385 ***Open tasks can support linguistically and culturally diverse learners, and learners***  
386 ***with identified learning differences.*** Open tasks can enable students with a range of  
387 different learning and linguistic skills to demonstrate their initial thinking in various ways  
388 (i.e., numerically, symbolically, verbally, visually, or through physical action; Darling,  
389 2019; CAST, 2018; Lambert and Sugita, 2016). They thereby support the alignment of  
390 instruction with the outcomes of the California ELD Standards and the UDL Guidelines.

391 To support participation of linguistically and culturally diverse English learners, teachers  
392 might listen for the mathematical ideas being expressed by students, noticing how  
393 students might draw on multiple language bases (i.e., translanguaging) or extra-  
394 linguistic communication, such as gesturing and using representation (Moschkovich,  
395 1999, 2013). Teachers can thus attend to students' mathematical ideas rather than  
396 focusing on correcting vocabulary and can listen carefully to know when to provide more  
397 substantial support for students at the Emerging level of English proficiency  
398 (Moschkovich, 2013). For example, the teacher could use revoicing to ensure that  
399 students understand a specific term under discussion (e.g., one-digit, two-digit). She  
400 could ask a direct question such as, "Mary said this is a two-digit number" as she points  
401 to a number. "Is this a two-digit number?" (Lagunoff et al., 2015). By revoicing and  
402 rephrasing students' statements, the teacher allows the student the right to evaluate the  
403 correctness of the teacher's interpretation. Revoicing also helps keep the discussion  
404 mathematical by reformulating the statement in ways closer to the standard  
405 mathematics discourse. For example, a teacher might say, "So I hear you say that this  
406 shape is not a triangle because it has four sides and triangles only have three sides. Is  
407 that right?"

408 While using open tasks, teachers can also support linguistically and culturally diverse  
409 language learners by strategically grouping students together for language

410 development. During small group and whole class discussion, students have  
411 opportunities to participate as audience members for classmates' presentations and  
412 explanations of their models and strategies. Through limited prompting and strategic  
413 support from the teacher, students determine whether their peers have used correct  
414 mathematical terminology when describing their processes. They also learn about ways  
415 their explanations could have been improved.

416 Effectively designing and implementing open tasks offers more ways for students to  
417 actively engage in mathematics and allows them to see how their perspectives and  
418 ideas can be assets in their own and their peers' learning. As the UDL Guidelines  
419 shown in figure 2.7 show, open tasks offer students multiple ways to access the  
420 mathematical content (see also Lambert, 2020). Rachel Lambert and others have  
421 described strategies to support the participation of students with identified learning  
422 differences to share their thinking:

- 423 ● Including paraprofessionals in the instruction allows students opportunities to  
424 rehearse and share their thinking in preparation for whole-class discussion  
425 (Baxter et al., 2005). This functions similarly to a think-pair-share completed prior  
426 to whole-class discussion.
- 427 ● Creating a classroom culture where all students can and *do* readily access  
428 resources—like math notebooks, media apps and websites, and manipulatives—  
429 whenever they need them. Some students may use particular resources more  
430 often or for longer amounts of time than other students during whole class  
431 discussions and benefit from being able to draw on them as necessary (Foote  
432 and Lambert, 2011).
- 433 ● Asking follow-up questions to set up the expectation and the support for students  
434 to be accountable to explaining their strategies. (Lambert and Sugita, 2016).

435 Instruction with open tasks can thus support differentiated learning, where progress is  
436 built upon students' current understandings, allowing them to address any previously  
437 unfinished learning even as they advance their thinking in powerful ways. When  
438 teaching focuses on such inclusive approaches, progress for each student, not

439 perfection, is the goal. Strategies that support students with identified learning  
 440 differences ultimately create a positive learning environment for all students.

441 The vignette [A Personalized Learning Approach](#) demonstrates an open-ended task that  
 442 all students can access and that extends to sufficient depth that all students remain  
 443 challenged (that is, a “low floor, high ceiling” task).

444 Figure 2.7 Universal Design for Learning Guidelines

 447 <https://udlguidelines.cast.org>.

## 448 **Component Three: Teach Toward Social Justice**

449 Mathematics is a tool that can be used to both understand and impact the world. But too  
450 often students believe mathematics is not for them (Bishop, 2012; Darragh, 2015).  
451 Research shows that social and cultural contexts play a role in learners' sense of  
452 belonging in mathematics classrooms. Additionally, learning environments enable or  
453 hinder whether and how students see themselves as doers of mathematics who believe  
454 that mathematics has a role in their lives (Lerman, 2000; Gutiérrez, 2013). Both  
455 mathematics educators and mathematics education researchers argue that teaching  
456 toward social justice can play an important role in shifting students' perspectives on  
457 mathematics as well as their sense of belonging as mathematics thinkers (Xenofontos,  
458 2019).

459 This framework discusses teaching toward social justice in two parts. First, it involves  
460 creating opportunities for students to both see themselves, as well as people from all  
461 backgrounds, as capable and successful doers of mathematics (Su, 2020). Second,  
462 teaching toward social justice urges educators to empower learners with tools to  
463 examine inequities and address important issues in their lives and communities through  
464 mathematics (Xenofontos et al., 2021; Goffney, Gutiérrez and Boston, 2018; Gutiérrez,  
465 2009).

466 ***Creating opportunities for students to see themselves and others as***  
467 ***mathematically competent.*** This concept is about building positive mathematical  
468 identities, beginning at the pre-kindergarten level. Teachers of young children use play  
469 to open opportunities for students to engage in non-routine problem solving, practice  
470 perseverance, and connect mathematical ideas (Chao and Jones, 2016, 17; Parks,  
471 2015; Wager, 2013) Through activities centered around play, teachers can create  
472 spaces for children to see their backgrounds represented in mathematics. Young  
473 students can thereby develop powerful mathematical identities and critical mathematics  
474 agency in ways that honor and connect to their own family and cultural histories. For  
475 example, the Number Book Project (Esmonde and Caswell, 2010) invited a grade two  
476 student to share a poem with kindergarten students that was then used to create a

477 classroom counting/number book for the kindergarten students. Teachers could use  
478 similar ideas to design engaging classroom activities.

479 Learning is not just a matter of gaining new knowledge—it is also about growth and  
480 identity development. As teachers introduce mathematics to students, they are helping  
481 them shape their sense of themselves as people who engage with numbers in the world  
482 (Langer-Osuna and Esmonde, 2017). Teaching mathematics through discussions and  
483 activities that broaden participation, lower the risks associated with contributing, and  
484 position students as thinkers and members of the classroom community are powerful  
485 ways to support students in seeing themselves as young mathematicians. Even in  
486 classrooms that utilize these approaches, however, stereotypes are often in play,  
487 impeding efforts to create robust, productive, and inclusive sense-making mathematics  
488 classroom communities (Langer-Osuna, 2011; Milner and Laughter, 2015; Shah, 2017).  
489 Teachers need to work consciously to counter racialized or gendered ideas about  
490 mathematics achievement (Joseph, Hailu, and Boston, 2017).

491 Teachers can begin with awareness that mathematics plays a role in the power  
492 structures and privileges that exist within our society and can support action and  
493 positive change. Teachers can support discussions that center mathematical reasoning  
494 rather than issues of status and bias by intentionally defining what it means to do and  
495 learn mathematics together in ways that include students' languages, experiences, and  
496 interests. One way to do this is by emphasizing and welcoming students' families into  
497 classroom discussions (González, Moll, and Amanti, 2006; Turner and Celedón-  
498 Pattichis, 2011; Moschkovich, 2013).

499 Teaching in culturally responsive ways that acknowledge and draw on students'  
500 backgrounds, histories, and funds of knowledge enable students to feel a sense of  
501 belonging (Brady et al., 2020; Gonzalez, Moll, and Amanti, 2006; Hammond, 2020; Moll  
502 et al., 1992). Students see mathematics as a set of lenses on the world relevant to their  
503 own lives. Although there is overlap with multicultural education, the type of culturally  
504 responsive teaching envisioned here extends far beyond considerations of food, music,  
505 and folklore; it is foundational to helping students acknowledge, understand, and

506 participate, both within the communities that they belong to and in the broader  
507 communities that they aspire to belong to. An eight-point framework for culturally  
508 responsive teaching developed by Muñiz (2019) aligns very closely with ideas of  
509 teaching toward social justice, including suggestions such as: reflect on one’s cultural  
510 lens; bring real-world issues into the classroom; and model high expectations for all  
511 students.

512 Culturally responsive teaching can be implemented in mathematics by exploring  
513 students’ lives and histories and designing and implementing curricula that center  
514 contributions that historically marginalized people have made to mathematics. Teachers  
515 can create opportunities for themselves and their students to share autobiographies as  
516 mathematics doers and learners, thereby creating spaces for students to participate as  
517 authors of their mathematical learning experiences.

518 Multicultural children’s literature can also be used to connect learning mathematics with  
519 students’ cultural experiences (Esmonde and Caswell, 2010; Leonard, Moore, and  
520 Brooks, 2013). For example, in *The Great Migration: An American Story* (Lawrence and  
521 Myers, 1995), young children explore quantity in terms of population shifts. In *First Day  
522 in Grapes* (Perez, 2002), a boy from a family of migrant workers uses his knowledge of  
523 mathematics to earn the respect of his peers. Drawing on *The Black Snowman*  
524 (Mendez, 1989), students can explore money problems through contexts linked to the  
525 African Diaspora. *One Grain of Rice* (Demi, 1997) offers students a context for exploring  
526 exponents and the importance of sharing food through the story of a peasant girl who  
527 tricks a king into giving her the royal storehouse’s entire supply of rice. *Multicultural  
528 Mathematics Materials* by Marina Krause (2000) also includes several games and  
529 activities that draw on Hopi and Navajo materials.

530 In the snapshot below, the teacher emphasizes the importance of communicating  
531 mathematical ideas and attending and responding to the mathematical ideas of others  
532 across languages. (Relevant big ideas and standards include DI.1, CC.3, SMP.3, 6; and  
533 4.OA.4, 5.) This snapshot comes out of classroom research on the participation of  
534 linguistically and culturally diverse English learners in mathematical discussions (Turner

535 et al., 2013). It documents an actual classroom experience. The teacher and students  
536 (grades four and five) are discussing multiplicative relations using a paper-folding task  
537 where students folded a piece of paper to make 24 equal parts. Note how the teacher  
538 and class members engage with Ernesto's thinking about the mathematics in this task.  
539 Ernesto is an English learner. By focusing attention on his reasoning, the teacher is  
540 validating his status as a contributor to the mathematical discourse within the class.

541 ***Snapshot: Engaging with an English Learner's Mathematical Thinking***

542 Teacher: Ernesto, ¿nos dices cómo lo hiciste? (Ernesto, would you tell us how you  
543 solved it?)

544 Ernesto: Lo doblé cinco veces, a la misma (I folded it five times, the same way—)  
545 [Stands up to come to the front of the room]

546 Teacher: [Hands Ernesto a piece of paper to show his folds] A ver, escúchenlo. (Let's  
547 see. Let's listen to him.)

548 Ernesto: Lo doblé. cinco veces, igual. Así. (I folded it five times, equally. Like this.)  
549 [Folds paper five times in the same direction, using an accordion-like fold] [Unfolds  
550 paper] Y me da seis partes. (And it gives me six parts.)

551 Teacher: His idea is to fold it five times, five times, and you get six parts. Does anyone  
552 have something to say to Ernesto? What do you think of how he did that? Anybody  
553 agree? [pause] Anybody else do it that way?

554 Corinne: It's different from ours, because he folded it five times to make six parts, and  
555 we—all three of us [the students who shared previously]—folded it in half, and [then]  
556 three times to make six parts.

557 Teacher: So, you noticed some way that Ernesto's strategy is a little bit different.

558 Reflection: The classroom community could be relied on to translate for others, and the  
559 emphasis remained on positioning all learners as thinkers and as members of the same  
560 community. In doing so, students who historically are marginalized in mathematical

561 discussions—in this case, English Learners—were positioned as contributors and  
562 thinkers alongside their English-speaking peers. Further, students from dominant  
563 cultures—in this case monolingual English speakers—had the opportunity to engage  
564 with the mathematical ideas of typically silent students, to take their ideas into  
565 consideration, and to build on and make connections to their mathematical thinking.

566 *(end snapshot)*

567 ***Empowering students with tools to examine inequities and address important***  
568 ***issues in their lives and communities*** (Berry et al., 2020; Gutstein, 2003, 2006). In  
569 this second aspect of teaching for social justice, teachers use mathematics to analyze  
570 and discuss issues of fairness and justice and to make mathematics relevant and  
571 engaging to students. In an elementary school classroom this might include students  
572 studying counting and comparing to understand fairness in the context of current and  
573 historical events (Chao and Jones, 2016). For example, in the fifth-grade Water Project,  
574 mathematics helped students explore questions of justice by incorporating topics of  
575 volume, capacity, operations, and proportional reasoning as students explored their  
576 families' access to and usage of water in developing countries (Esmonde and Caswell,  
577 2010). Relatedly, teachers in Flint, Michigan, used the crisis of unsafe water in that city  
578 to connect a personally relevant and meaningful situation to their mathematics lessons  
579 (Plumb et al., 2017). The teachers asked, “How many water bottles does our class need  
580 each day?” and facilitated a mathematical exploration in which students estimated and  
581 calculated whether the number of water bottle donations reported in the news was  
582 sufficient to meet the needs of the school.

583 As further described in chapter five, teachers' use of rich, open tasks that include  
584 opportunities for students to connect mathematics to their lives can also support the  
585 foundational development of data literacy, where students are asking investigative  
586 questions, collecting, considering, and analyzing data, and communicating findings (see  
587 also Franklin and Bargagliotti, 2020). When grappling with data, students can pose  
588 questions about issues that matter to them, ranging from water quality to such issues as  
589 cyber bullying, neighborhood resources, or sports and recreation. Data related to issues

590 can draw not only from a range of mathematical ideas and student curiosities but also  
591 from a range of feelings about relevant, complex issues. A focus on complex feelings  
592 aligns with trauma-informed pedagogy, which highlights the importance of allowing  
593 students to identify and express their feelings as part of mathematics sense-making,  
594 and to allow students to address what they learn about their world by suggesting  
595 recommendations and taking action (Kokka, 2019).

596 Mathematics lessons that incorporate open tasks and the use of real-world data can  
597 thus create opportunities for teachers to find out about their students' cultures, interests  
598 and experiences. At the same time, these lessons can provide contexts that help  
599 students understand mathematics as a tool for participating meaningfully in their  
600 communities and for seeing patterns that exist throughout the world. Meanwhile, as  
601 teachers gain knowledge about their students' interests and cultures, they become  
602 better math teachers, able to choose, craft, and launch tasks that engage students with  
603 big ideas in meaningful and relevant ways (Aguirre, 2012; Ladson-Billings, 2009;  
604 Hammond, 2020).

605 Mathematics educators committed to social justice work provide curricular examples  
606 that equip students with a toolkit and mindset to identify and combat inequities with  
607 mathematics (Gutstein, 2006; Gutstein and Peterson, 2005; Moses and Cobb, 2001).  
608 Tasks have been developed to help students read and write the world with  
609 mathematics. First, students read the world by learning to use mathematics to highlight  
610 inequities. They then write the world—in other words, they learn to change it with  
611 mathematics (Gutstein, 2003; 2006). Note that these tasks correspond to Drivers of  
612 Investigation DI 1(making sense of the world), DI 2 (predicting what could happen), and  
613 DI3 (Impacting the future).

614 While the ideas of teaching toward social justice are not new, they are newly  
615 emphasized in this framework. One useful resource for teachers as they become  
616 familiar with these ideas is The Teaching Maths for Social Justice Network (TMSJN,  
617 n.d.). TMSJN provides information on approaches and how they might be related and

618 used in tandem—e.g., integrating open tasks, assets-based instruction, and culturally  
619 relevant pedagogy—to support equitable mathematics classrooms.

#### 620 **Component 4: Invite Student Questions and Conjectures**

621 Since open tasks about big ideas in mathematics foster curiosity, teachers can invite  
622 that curiosity by making space for students' questions and conjectures. Students asking  
623 or posing mathematical questions is one of the most important yet neglected  
624 mathematical acts in classrooms—not questions to help move through a problem, but  
625 questions sparked by wonder and intrigue (Duckworth, 2006). For example, “What is  
626 half of infinity?” “Is zero even or odd?” “Does the pattern that describes the border of a  
627 square work if the shape is a pentagon?” Questions sparked by curiosity might sound  
628 like they're pushing back on the ideas in play in the classroom, since students may  
629 begin questions with, “But what about...?” or “But didn't you just say...?” But such  
630 questions should be valued and students given time to explore them. They are  
631 important in the service of creating active, curious mathematical thinkers.

632 Students given the opportunity to explore big ideas through open tasks become  
633 mathematically curious and are well primed to engage in another important act: making  
634 a conjecture. Most students in science classrooms know that a hypothesis is an idea  
635 that needs to be tested and proven. The mathematical equivalent of a hypothesis is a  
636 conjecture. When students are encouraged to come up with conjectures about  
637 mathematical ideas, and the conjectures are discussed and investigated by the class,  
638 students come to realize that mathematics is a subject that can be explored deeply and  
639 logically. It is through conjectures that curiosity and sense-making are nurtured.

640 Teachers invite student questions and conjectures when they teach by way of open,  
641 engaging tasks that focus on big ideas. The Drivers of Investigation, centered in this  
642 framework, are intended to spark students' curiosity and prompt them to develop  
643 conjectures as they work on investigations with the goals of “making sense of the  
644 world,” “predicting what could happen,” and/or “impacting the future.” Encouraging  
645 questioning and conjecturing promotes critical and creative thinking. It also develops  
646 students' sense of ownership of mathematical knowledge and understanding as

647 teachers and students interrogate social positionings of who does mathematics.  
648 Students' sense of ownership, nurtured through this approach, reflects the living  
649 practice of mathematics as a fluid endeavor wherein all persons are capable of  
650 questioning, creating, and owning mathematical knowledge.

651 Teachers, of course, can raise purposeful and productive questions as well, moving  
652 beyond questions that demand only simple recall or superficial explanation which  
653 sometimes dominate classroom conversation (Simpson et. al., 2014). To support  
654 students' content development and to implement the SMPs, teachers should give  
655 careful attention to the types of questions they use. The goal is to use high quality,  
656 probing questions that empower students to deepen their understanding.

657 The Mathematics Assessment Project (MAP) offers a series of professional  
658 development modules (Mathematics Assessment Project, n.d.) that include *Improving*  
659 *Learning through Questioning*. This module provides guidance on how and why to use  
660 open-ended questions and provides examples such as, "What patterns can you see in  
661 this data?" or "Which method might be best to use here? Why?" Questions of this type  
662 take students beyond simple recall of known facts, instead calling for original thought  
663 and connections of concepts. MAP research has found that to draw students into  
664 mathematical conversations, questions must be designed to include all students and to  
665 elicit thinking and reasoning. Teachers should provide think time, support students to  
666 verbalize their thinking, avoid judging student responses, and pose follow-up questions  
667 that encourage students' continued mathematical thinking. NCTM's *Principles to Actions*  
668 (2014) offers further guidance on how teachers can pose purposeful questions to  
669 support mathematical reasoning and justification among students. Additionally, Chapin,  
670 O'Connor, and Anderson's 2013 book, *Talk Moves*, provides multiple strategies  
671 teachers can employ to support students' mathematical discussions, questions, and  
672 conjectures.

673 As teachers learn to engage in this practice, they might consider writing good questions  
674 down on a card and carrying it around during class for reference (back pocket  
675 questions). Or post questions on the wall as a reminder until they become automatic.

676 Examples of good math questions can be found in books by Peter Sullivan and Marion  
677 Small. For example, in Sullivan's *Good Questions for Math Teaching* (2002), he offers  
678 examples of good questions, organized by mathematical topics, that drive discussion,  
679 inquiry, and reasoning in math classrooms.

680 The following snapshot provides an example of how students created mathematical  
681 conjectures and how the teacher supported students' active discussion of the  
682 conjectures.

683 ***Snapshot: Student Conjectures***

684 A teacher presented fourth-grade students with a list of eight equations, noting that not  
685 all of them were true statements of equality. The students worked with partners to  
686 decide which were true and which were false and to explain how they knew.

687  $2 \times (3 \times 4) = 8 \times 3$

688  $4 \times (10 + 2) = 40 + 2$

689  $5 \times 8 = 10 \times 4$

690  $6 \times 8 = 12 \times 4$

691  $9 + 6 = 10 + 5$

692  $9 - 6 = 10 - 5$

693  $9 \times 6 = 10 \times 5$

694 Ryan and Anen worked together, and after a few minutes, the teacher could see that  
695 they were very excited. The teacher stopped by their workplace and, after listening to  
696 their explanation and posing a few challenges, invited them to describe their "magic"  
697 trick with multiplication to the class. At the front of the class, Anen wrote equation c,  $5 \times$   
698  $8 = 10 \times 4$ , on the board, and asked everyone to use a hand signal to show true or  
699 false. Almost all students indicated it is a true equation. Ryan asked the class about  
700 example d,  $6 \times 8 = 12 \times 4$ . Again, the class agreed that it is true.

701 Anen and Ryan continued, saying that something special was going on, and they had a  
702 conjecture they think *probably* works all the time, but they want to be sure. They  
703 explained that in  $5 \times 8 = 10 \times 4$ , they noticed “5” on the left side of the equation is half of  
704 the “10” on the right side, and the “8” on the left side is two times the “4” on the right  
705 side. So, they concluded, trying to use proper mathematical language, and pointing at  
706 the numbers as they spoke, “If you have factors like that where one first factor is half of  
707 the other first factor, and the second factor is twice as big as the other second factor,  
708 they’ll always be equal!”

709 The teacher called for the class to explore this conjecture and to see whether they could  
710 find a way to prove whether it is always true or not. Now the whole class was interested  
711 and trying to prove or disprove Ryan’s and Anen’s conjecture.

712 The teacher supported the discussion in several ways by:

- 713 ● bringing the class together to listen according to class norms such as “everyone  
714 gets to speak” and “we listen carefully to each other’s ideas”
- 715 ● encouraging the speakers to pause occasionally so that their classmates would  
716 have time to think and try out ideas
- 717 ● asking students to repeat, revoice, or add on to each other’s statements
- 718 ● re-stating Ryan’s and Anen’s explanations using precise mathematical terms
- 719 ● checking with students who are learning English to ensure that they are both  
720 communicating with and supported by their partners during the student-led  
721 presentation
- 722 ● calling for others in the class to express their own conjectures and challenges
- 723 ● focusing students’ attention to Anen and Ryan’s explanations and questions
- 724 ● posing questions to both the presenters and the other class members as the  
725 discussion progressed, such as:
  - 726 ○ why is this true?
  - 727 ○ will this always work?
  - 728 ○ does this work for other operations, or only for multiplication?
  - 729 ○ how can we know?

730                   ○ how are these numbers related?

731    (*end snapshot*)

732    In the above snapshot’s list of teacher supports, student peer revoicing was one of the  
733    strategies listed to encourage students’ questions and help students engage in  
734    mathematical discussion. Peer revoicing can encourage students to ask questions and  
735    help students engage in mathematical discussion. It is a “talk move” between two  
736    people where the contribution of the speaker is restated by the listener, who checks with  
737    the speaker to confirm understanding. It often includes a statement such as, “So I hear  
738    you say...” followed by a restatement of the speaker’s words and then a check for  
739    understanding such as “Is that right?”

740    Peer revoicing is a powerful routine for promoting shared understanding of mathematics  
741    as well as mutual recognition as young mathematicians. It structures the dialogue  
742    between the speaker and the listener in a way that ensures that the contributions build  
743    meaningfully upon each other. Teacher and peer revoicing can elevate the  
744    mathematical contributions of a student perceived as low-status (Cohen and Lotan,  
745    1997; Cabana, Shreve, and Woodbury, 2014; LaMar, Leshin, and Boaler, 2020).

746    The following snapshot highlights how peer revoicing helped first graders take turns  
747    sharing, listening, and reasoning about one another’s math ideas. (Derived from  
748    Langer-Osuna, Trinkle, and Kwon’s research, 2019).

749    ***Snapshot: Peer Revoicing***

750    Hope, a grade one teacher, introduces peer revoicing during a whole-class carpet  
751    discussion. She wants her young learners to practice a way of interacting that supports  
752    mutual attention and making sense of one another’s mathematical thinking (SMP.3, 5,  
753    6). Using a large rekenrek, she models revoicing with a student partner. The student  
754    partner first states how many beads she sees on the rekenrek and how she knows (D11,  
755    CC2; 1.OA.3, 6).

756

757 S: I see eight beads because there are five on the top and three on the bottom and  
758 that's five, six, seven, eight.

759 T: So, I hear you say that you see eight beads because there are five beads on the top  
760 and three beads on the bottom and you counted up from five, six, seven, eight. and  
761 that's how you knew there were eight. Is that right?

762 S: [nods head] Yup.

763 Hope then models the language used for the revoicing. "Let's practice that" she says to  
764 her class. "I hear you say 'mmmmm,' is that right?"

765 The class repeats as a chorus, "I hear you say 'mmmmm,' is that right?"

766 Students then practice at the carpet with their partners, drawing on sentence frames  
767 taped onto the wall as needed and a class set of rekenreks before taking their  
768 rekenreks back to their tables for partner work.

769 At their table, students take turns representing numbers. Ana represents the number 10  
770 and turns it toward her partner Sam. Sam counts the beads one by one and then states:

771 Sam: "I see a 10 because there are 1, 2, 3, 4, 5 on the top and 5 on the bottom."

772 Ana: "So I hear you say, wait. Can you repeat?"

773 Sam: [giggles] I said I see a 10 because there are 5 on the top and 5 on the bottom and  
774 that makes 10.

775 Ana: "So I hear you saying that you see a 10 because there are 5 on the top and 5 on  
776 the bottom, is that right?"

777 Sam: “and that makes 10”

778 Ana: “and that makes 10. Is that right?”

779 Sam: Yes

780 Ana: Ok, my turn. You do a number now.

781 *(end snapshot)*

782 In addition to promoting active student questioning and reasoning, teacher and peer  
783 revoicing strategies actively aim to challenge deficit-oriented thinking because all  
784 students are empowered with making valuable contributions toward sense-making and  
785 learning.

## 786 **Component 5: Prioritize Reasoning and Justification**

787 Reasoning is at the heart of doing and learning mathematics. Through the acts of  
788 reasoning and justifying, more students can begin to see mathematics as a tool to ask  
789 questions about and make sense of their world, rather than as a static set of rules.  
790 When students have opportunities to reason and justify while engaging with open tasks,  
791 their engagement in math increases (Aguirre et al., 2013; Boaler and Staples, 2008)  
792 and they strengthen their identities as members of the mathematics community.  
793 Students’ mathematics achievement is also more likely to increase (Hiebert and  
794 Wearne, 1993; Stein and Lane, 1996) relative to that in classrooms that primarily use  
795 closed tasks requiring low levels of cognitive demand. Not least, students who are  
796 routinely prompted to reason about and justify their ideas build communication skills and  
797 learn to think flexibly and creatively—essential assets for twenty-first century  
798 employment (Mlodinow, 2018; Wolfram, 2020).

799 Unfortunately, many students don’t get to engage in deep reasoning while doing rich  
800 and open mathematics tasks. The Education Trust report *Checking In* (2018) describes  
801 middle school mathematics students’ limited opportunities to engage with rigorous tasks  
802 that require discussing and justifying their reasoning. Overall, only 9 percent of

803 assignments had high cognitive demand, and the portion of assignments with low  
804 cognitive demand was higher in schools with more students experiencing poverty.  
805 Researchers have consistently documented that students in minoritized groups by race,  
806 socio-economic status, and first language are, disproportionately, not provided  
807 opportunities to engage in rigorous mathematical practices such as reasoning and  
808 justification (Oakes, 1999; Wilson and Urick, 2021).

809 *The Opportunity Myth* (TNTP, 2018) documented the experiences of over 30,000  
810 students in grade six to twelve, finding that while 71 percent of students succeeded on  
811 their classroom assignments, only 17 percent demonstrated grade-level mastery on  
812 those assignments. The authors' analysis found this result partly due to the procedural  
813 nature of the tasks used in classes. Tasks were not on grade level or involved low  
814 cognitive demand. Rarely did students have opportunities to discuss their reasoning and  
815 justify their mathematical thinking. Strikingly, 38 percent of the classrooms with no  
816 grade level assignments were predominantly students of color; only 12 percent were  
817 predominantly White students.

818 It is imperative to work toward more equitable mathematics teaching and learning. This  
819 framework builds on research suggesting that all students can reason deeply with and  
820 about mathematics and must be provided with opportunities to do so (Boaler and  
821 Staples, 2008; Bieda and Staples, 2020; Thanheiser and Sugimoto, 2022). Ensuring  
822 that all students have routine chances to engage in deep reasoning calls for two key  
823 conditions: teachers using effective teaching practices and classroom structures that  
824 promote student justification and reasoning.

825 ***Teachers using effective teaching practices.*** NCTM identifies teachers'  
826 implementation of tasks that promote reasoning and problem solving as one of eight  
827 effective teaching practices (*Catalyzing Change*, NCTM, 2020). To incorporate  
828 reasoning into classroom instruction, teachers must start with productive beliefs about  
829 mathematics teaching and learning. Figure 2.8 expands on productive beliefs presented  
830 earlier in this chapter, focusing here on teachers facilitating tasks rather than providing  
831 information, students playing an active role in sense-making, and teachers challenging

832 students to persevere and struggle productively to reason about and express their ideas  
 833 (NCTM *Principles to Action*, 2014).

834 Figure 2.8 Beliefs About Teaching and Learning Mathematics (continued)

Unproductive beliefs	Productive beliefs
The role of the teacher is to tell students exactly what definitions, formulas, and rules they should know and demonstrate how to use this information to solve mathematics problems.	The role of the teacher is to engage students in tasks that promote reasoning and problem solving and facilitate discourse that moves students toward shared understanding of mathematics.
The role of the student is to memorize information that is presented and then use it to solve routine problems on homework, quizzes, and tests.	The role of the student is to be actively involved in making sense of mathematics tasks by using varied strategies and representations, justifying solutions, making connections to prior knowledge or familiar contexts and experiences, and considering the reasoning of others.
An effective teacher makes the mathematics easy for students by guiding them step by step through problem solving to ensure that they are not frustrated or confused.	An effective teacher provides students with appropriate challenge, encourages perseverance in solving problems, and supports productive struggle in learning mathematics.

835 Source: NCTM, 2014b.

836 As noted in the sections above, effective mathematics teaching requires that teachers  
 837 recognize the out-of-school cultural practices of students as assets, not deficits, and  
 838 incorporate those assets as instructional resources or tools. When teachers assume  
 839 that cultural, linguistic, and community-based differences are assets, they open up  
 840 possibilities for students to use their lived experiences as resources for reasoning and  
 841 sense making.

842 ***Classroom structures that promote student justification and reasoning.***

843 Classrooms that use open tasks organized around big mathematical ideas and allow  
 844 multiple entry points for students often share a similar structure designed to encourage  
 845 students' mathematical reasoning:

- 846 ● The teacher launches a problem (or problem context) and uses participation  
847 structures to support equitable engagement (Featherstone et al., 2011).
- 848 ● Students are allowed to individually process the questions being asked,  
849 understand the problem, and organize their thoughts prior to engaging in  
850 discussion.
- 851 ● Students work through the problem in peer partnerships or small groups.
- 852 ● The class gathers for whole-class discussion, reflection, and synthesis,  
853 referencing students' solutions (Smith and Stein, 2018).

854 Students can explore mathematical questions, make conjectures, and reason about  
855 mathematics as they work in collaboration with peers during both small group and whole  
856 class discussions. Such discussions create opportunities for teachers and students to  
857 press other students about *why* they solved a problem in a particular way. This  
858 emphasis on *justification*—as a classroom practice—can support equitable outcomes  
859 because it gives students additional access to ways of making sense of mathematical  
860 concepts and procedures and provides time for students to make aspects of their  
861 thinking more explicit to themselves and others (National Academy of Sciences, 2018).  
862 Justification can aid in the development of more equitable student outcomes by making  
863 space for a broad range of student ideas to be brought into the classroom discussion.

864 Establishing classroom norms and routines can support students in attending to and  
865 making sense of their peers' mathematical ideas and questions in ways that position  
866 one another's thinking as worthy of taking into consideration (see also Cabana, Shreve,  
867 and Woodbury, 2014). Teachers must create norms and structures that enable all  
868 students to share and discuss ideas inclusively and draw students into mathematical  
869 conversations on an equal footing. An important message for students is the value of  
870 taking mathematical risks. Making mathematical errors and confusions public helps  
871 students make sense of them together, as a classroom of learners. A classroom that  
872 welcomes students' unfinished thinking normalizes mathematical struggle as part of  
873 learning and positions all learners as belonging to the discipline of mathematics.

874 Issues of status, stereotypes, and peer relationships can get in the way of mathematical  
875 sense-making by biasing who participates, and in what ways, in the mathematical work  
876 at hand (Cohen and Lotan, 1997; Esmonde and Langer-Osuna, 2011; Shah, 2017;  
877 LaMar, Leshin, and Boaler, 2020; Turner et al., 2013). Whole-class discussions at the  
878 close of a lesson provide opportunities to reflect on the impact of student partnerships  
879 and small-group work so that students increasingly internalize the expectations and  
880 learn the tools of inclusive, productive, shared mathematical work. Teachers might ask,  
881 “What went well in your partnerships today that we can learn from? What was difficult?  
882 What might we try tomorrow to be better partners?” Responses not only allow students  
883 an opportunity to express their thoughts like a mathematician, but the responses can  
884 provide valuable formative feedback for teachers to use when defining the next steps in  
885 the learning progression(s).

886 Structuring lessons to introduce questions first, allowing students time to consider how  
887 to approach the question, and incorporating student discussion and reasoning are  
888 distinct from the direct instruction approach. Direct instruction involves teaching  
889 students the methods and then providing opportunities to practice those methods. The  
890 two approaches are not mutually exclusive: there are appropriate times to incorporate  
891 direct instruction (Schwartz and Bransford, 1998; Deslauriers et al., 2019). For example,  
892 direct instruction may be especially useful when students *need* the methods to solve  
893 problems; they may be engaged and interested to learn the new methods being  
894 described (NCTM, 2014b).

895 Smith and Stein’s text, *5 Practices for Orchestrating Productive Mathematical*  
896 *Discussions* (2018), offers a useful approach to planning and implementing tasks to  
897 support student reasoning. Chapin, O’Connor, and Anderson (2013) provide further  
898 support for teachers in supporting productive classroom discussions, considering the  
899 mathematics to talk about, and incorporating the moves that encourage productive  
900 discussions.

901 The snapshot below describes a high school classroom in which the teacher structured  
902 a lesson to actively engage students in reasoning needed to solve a problem. The big

903 mathematical ideas and standards supported by the lesson are included at the end of  
904 the snapshot.

905 ***Snapshot: 36 Fences***

906 Lori, a high school geometry teacher, introduces a problem to students at the start of a  
907 90-minute class period. Lori explains that a farmer has 36 individual fence panels, each  
908 measuring one meter in length, and that the farmer wants to put them together to make  
909 the biggest possible area. Lori takes time to ask her students about their knowledge of  
910 farming, making reference to California’s role in the production of fruit, vegetables, and  
911 livestock. The students engage in an animated discussion about farms and the reasons  
912 a farmer may want a fenced area. While some of Lori’s long-term English learners show  
913 fluency with social/conversational English, she knows some will be challenged by  
914 forthcoming disciplinary literacy tasks. To support meaningful engagement in  
915 increasingly rigorous course work, she ensures that images of all regular and irregular  
916 shapes are posted and labeled on the board, along with an optional sentence frame,  
917 “*The fence should be arranged in a [blank] shape because [blank].*” These support  
918 instruction when Lori asks students what shapes they think the fences could be  
919 arranged to form.

920 Students suggest a rectangle, triangle, or square. With each response, Lori reinforces  
921 the word with the shape by pointing at the image of the shapes. When she asks, “How  
922 about a pentagon?” she reminds students of the optional sentence frame as they craft  
923 their response. Lori asks the students to think about this from the farmer’s perspective,  
924 and talk about it as mathematicians. Lori asks them whether they want to make irregular  
925 shapes allowable or not.

926 After some discussion, Lori asks the students to think about the biggest possible area  
927 that the fences can make. Some students begin by investigating different sizes of  
928 rectangles and squares, some plot graphs to investigate how areas change with  
929 different side lengths.

930 Susan works alone, investigating hexagons—she works out the area of a regular  
931 hexagon by dividing it into six triangles and she has drawn one of the triangles  
932 separately. She tells Lori that she knew that the angle at the top of each triangle must  
933 be 60 degrees, so she could draw the triangles exactly to scale using compasses and  
934 find the area by measuring the height.

935 Niko finds that the biggest area for a rectangle with perimeter 36 is a 9 x 9 square—  
936 which gives him the idea that shapes with equal sides may give bigger areas and he  
937 starts to think about equilateral triangles. Niko is about to draw an equilateral triangle  
938 when he gets distracted by Jaden who tells him to forget triangles, he has a conjecture  
939 that the shape with the largest area made of 36 fences is a 36-sided shape. Jaden  
940 suggests to Niko that he find the area of a 36-sided shape too and he leans across the  
941 table excitedly, explaining how to do this. He explains that you divide the 36-sided  
942 shape into triangles and all of the triangles must have a one-meter base. Niko joins in  
943 saying, “Yes, and their angles must be 10 degrees!” Jaden says, “Yes, and to work it  
944 out we need tangent ratios which the teacher has just explained to me.”

945 Jaden and Niko move closer together, incorporating ideas from trigonometry, to  
946 calculate the area.

947 As the class progresses many students start using trigonometry. Some students are  
948 shown the ideas by Lori, some by other students. The students are excited to learn  
949 about trig ratios since they enable them to go further in their investigations, they make  
950 sense to them in the context of a real problem, and they find the methods useful. In later  
951 activities the students revisit their knowledge of trigonometry and use them to solve  
952 other problems.

953 Opportunities for learning – Big Mathematical Ideas and California Mathematics  
954 Standards

- 955 • Geospatial Data (G-SRT.5, G-CO.12, G-MG.3)
- 956 • Triangle Problems (G-SRT.4, G-SRT.5, G-SRT.6, G-SRT.8, G-CO.12)
- 957 • Trig Explorations (G-SRT.5)

- 958 • Triangle Congruence (G-CO.12)
- 959 • Circle Relationships (G-CO.12)
- 960 • Transformation (G-CO.12)
- 961 • Geometric models (G-SRT.5, G-CO.12)

962 In this snapshot, students have an opportunity to meaningfully and actively engage in  
963 rich mathematical thinking. While some students worked alone, many students are both  
964 incorporating ideas from other students and contributing their own thinking. Through  
965 these actions, students are actively investigating and making connections across their  
966 own work while also seeing their own and others' ideas as learning assets.

967 *(end snapshot)*

## 968 **Conclusion**

969 This chapter has detailed the five components of instructional design that encourage  
970 equitable outcomes and active student engagement: teaching big ideas, using open  
971 tasks, teaching toward social justice, supporting students' questions and conjectures,  
972 and prioritizing reasoning and justification. Enacting these components requires that  
973 teachers broaden their perceptions of mathematics beyond methods and answers. The  
974 aim is to have students come to view mathematics as a subject that is about sense  
975 making and reasoning, to which they can contribute and belong. To achieve this,  
976 teachers need to create more opportunities for students to engage in intriguing, deep  
977 tasks that honor their ideas and thinking and draw on their backgrounds, interests, and  
978 experiences. Teachers pose purposeful questions and structure lessons to provide time  
979 for students to engage in mathematical reasoning through small and whole-group  
980 discussions. Such practices can enable all students to see themselves as  
981 mathematically capable learners with a curiosity and love of learning mathematics—  
982 capacities that will bolster them throughout their schooling.

## 983 **Additional Resources**

984 Teachers may be interested in the following vignettes, each of which provides a  
985 classroom example of practices discussed in this chapter.

986 **Vignette:** [\*Productive Partnerships\*](#). To successfully launch tasks, teachers should  
987 discuss key contextual features and mathematical ideas, soliciting ideas from students  
988 to create shared language for anything that might be unfamiliar or confusing without  
989 reducing the cognitive demand of the task. Whole-class discussions during the launch  
990 are also important opportunities to support students in learning how to effectively and  
991 inclusively share ideas during small group work. This vignette describes an example of  
992 such a discussion in a fourth-grade classroom.

993 **Vignette:** [\*Exploring Measurements and Family Stories\*](#). In this vignette a group of  
994 students explores their family’s immigration experiences through a measurement lesson  
995 on the topic of unit conversion, specifically between the US system and the metric  
996 system. Many of the students had experienced immigrating with their families to the US,  
997 knew relatives who had, or have family members living in other countries. Through map  
998 explorations and a series of discussions, students use and expand their math skills.

999 **Vignette:** [\*Math Identity Rainbows\*](#). In Ms. Wong’s classroom in this vignette, students  
1000 start to see mathematics as something that relates to their lives and that can work to  
1001 empower individuals and communities. Tasks are not only deliberately designed to  
1002 engage students in meaningful mathematics, but are also, at times, designed to support  
1003 students in noticing that they are already important members of the mathematics  
1004 classroom community.

## 1005 **Long Descriptions of Graphics for Chapter 2**

### 1006 **Figure 2.3: Grade Six Map of Big Ideas**

1007 The graphic illustrates the connections and relationships of some sixth-grade  
1008 mathematics concepts. Direct connections include:

- 1009 • Variability in Data directly connects to: The Shape of Distributions, Relationships  
1010 Between Variables

- 1011 • The Shape of Distributions directly connects to: Relationships Between  
1012 Variables, Variability in Data
- 1013 • Fraction Relationships directly connects to: Patterns Inside Numbers,  
1014 Generalizing with Multiple Representations, Model the World, Relationships  
1015 Between Variables
- 1016 • Patterns Inside Numbers directly connects to: Fraction Relationships,  
1017 Generalizing with Multiple Representations, Model the World, Relationships  
1018 Between Variables
- 1019 • Generalizing with Multiple Representations directly connects to: Patterns Inside  
1020 Numbers, Fraction Relationships, Model the World, Relationships Between  
1021 Variables, Nets & Surface Area, Graphing Shapes
- 1022 • Model the World directly connects to: Fraction Relationships, Relationships  
1023 Between Variables, Patterns Inside Numbers, Generalizing with Multiple  
1024 Representations, Graphing Shapes
- 1025 • Graphing Shapes directly connects to: Model the World, Generalizing with  
1026 Multiple Representations, Relationships Between Variables, Distance &  
1027 Direction, Nets & Surface
- 1028 • Nets & Surface directly connects to: Graphing Shapes, Generalizing with Multiple  
1029 Representations, Distance & Direction
- 1030 • Distance & Direction directly connects to: Graphing Shapes, Nets & Surface Area
- 1031 • Relationships Between Variables directly connects to: Variability in Data, The  
1032 Shape of Distributions, Fraction Relationships, Patterns Inside Numbers,  
1033 Generalizing with Multiple Representations, Model the World, Graphing Shapes
